INDUSTRIAL CARBON EMISSIONS

In order to limit global warming to 1.5 °C, carbon emissions in the world should decrease by 45% by 2030, and “net-zero” should be reached by 2050

DIRECT CARBON EMISSIONS

Consumption of fossil fuel to power the machines, the heating it causes, leakages in the transmission of natural gas or oil

INDIRECT CARBON EMISSIONS

The use of non-renewable resources for the production electrical energy to be used for other applications that cause carbon emissions

TAKING STEPS TO ENSURE SUSTAINABILITY

Reducing the consumption of resources such as oil by performing regular maintenance of the machines and ensuring that the energy consumption does not exceed the expected values takes your business one step closer to achieve **net-zero targets**.

With **effective maintenance strategies**, maintenance costs can be reduced by up to 40% and energy consumption by 10%. In addition, with effective maintenance strategies, the risk of unexpected downtimes in production is reduced and the cost of a product is reduced.

CONTRIBUTION OF PREDICTIVE MAINTENANCE

Mechanical and electrical faults cause more energy to be drawn from the mains in the machines, but this energy is transformed into vibration and heat instead of being used in the machine. **Regularly maintained** and healthy machines **consume less electrical energy** compared to their malfunctioning conditions and play a role in reducing carbon emissions.

Besides all the financial costs, knowing the **environmental costs** of energy production, maintenance activities and manufacturing creates a sense of responsibility about saving energy in order to achieve net-zero goals. **Predictive maintenance** is at a key point in sustainability by focusing on reducing energy consumption, increasing machine lifetime, optimizing supply chain and maintaining the machines on time.

MAKING MAINTENANCE ACTIVITIES SUSTAINABLE

Sensemore collects and analyzes the data from the machines with the software and hardware solutions and the services it offers to its customers. Users are informed with root-cause analysis of possible failures and contribute to **sustainability goals** by preventing unplanned downtime.

Thanks to the **energy monitoring** application that Sensemore offers to its customers with the IoT data acquisition device, voltage sensors, and current sensors, it is allowed for determining the amount of energy that the machines consume and **reducing carbon emissions** by taking action on the machines that consume more energy than normal.
